Psoriatic arthritis is a type of inflammatory arthritis that appears in up to a third of the people with psoriasis, affecting both the skin and joints

HOW CAN YOU REDUCE YOUR RISK OF DEVELOPING HEART DISEASE?

Medications that suppress skin and joint inflammation may suppress inflammation in blood vessels and reduce the risk of developing heart disease. Therefore, regular monitoring and active treatment of psoriasis and PsA by specialists for optimal control of inflammation is important

Some arthritis medications, especially nonsteroidal anti-inflammatory drugs (NSAIDs), like ibuprofen and naproxen, may be associated with an increased risk of developing heart disease. If possible, minimize the use of anti-inflammatory medications

CARDIO-RHEUMATOLOGY CLINIC AT WOMEN'S COLLEGE HOSPITAL

- The Cardio-Rheumatology Clinic at Women's College Hospital was established to help those with inflammatory rheumatic conditions manage their heart disease risk
- Patients undergo a thorough assessment by a cardiologist and are evaluated for abnormal heart function using a variety of advanced imaging and laboratory tests
- In addition, the clinic's staff are searching for better ways to assess heart risk in PsA patients through its research program

CardioRheum

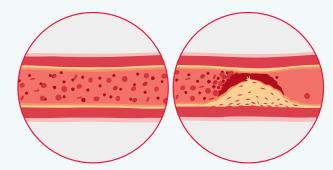

PSORIATIC ARTHRITIS (PsA) AND HEART DISEASE

- People with PsA have an approximately
 50% higher risk of developing heart disease compared to people without PsA
- PsA is associated with known risk factors for heart disease, including high blood pressure, diabetes and abnormal cholesterol levels
- The increased risk of developing heart disease is related in part to these known risk factors, but the severity of inflammation in the skin and the joints is also important
- People with severe psoriasis that covers large parts of their body are up to two times more likely to develop a heart attack
- People with more active arthritis have a higher risk of developing heart disease

WHY DO PEOPLE WITH PSA DEVELOP HEART DISEASE?

- Atherosclerosis, the buildup of cholesterol within blood vessel walls (also known as plaque), is the process that leads to the majority of heart diseases
- Atherosclerosis leads to the narrowing of blood vessels, increased blood pressure and decreased blood flow to the heart and other organs. Some unstable plaques can rupture, triggering a clot that may cause a heart attack or stroke

Normal Blood Vessel

Narrowed Blood Vessel with Plague Buildup

 Uncontrolled inflammation, as seen in active psoriasis or PsA, may lead to rapid progression of atherosclerosis and increases the risk of plague rupture

HOW CAN YOUR DOCTOR DETERMINE IF YOU ARE AT RISK FOR HEART DISEASE?

- Your age and sex as well as information about your blood pressure, blood sugar, cholesterol levels, and lifestyle habits help the physician to estimate your future risk of developing heart disease
- More advanced tests, like a CT scan and ultrasound of the heart and arteries, can improve the accuracy of identifying people who are at high risk of developing heart disease
- The risk also depends on the severity of inflammation in the skin and joints
